0.1 Q1. read.csv (base R) vs read_csv (tidyverse) vs fread (data.table)

0.1.1 Q1.1 Speed, memory, and data types

There are quite a few utilities in R for reading plain text data files. Let us test the speed of reading a moderate sized compressed csv file, admissions.csv.gz, by three functions: read.csv in base R, read_csv in tidyverse, and fread in the data.table package.

Which function is fastest? Is there difference in the (default) parsed data types? How much memory does each resultant data frame or tibble use? (Hint: system.time measures run times; pryr::object_size measures memory usage; all these readers can take gz file as input without explicit decompression.)

```
library(microbenchmark)
library(readr)
library(data.table)
base = read.csv("~/mimic/hosp/admissions.csv.gz")
readr = read_csv("~/mimic/hosp/admissions.csv.gz", show_col_types = FALSE)
dt = fread("~/mimic/hosp/admissions.csv.gz")
benchmark_results <- microbenchmark(</pre>
  base , readr , dt , times = 5
print(benchmark_results)
Unit: nanoseconds
  expr min lq mean median
                            uq
                                   max neval
 base 30 40 172.4 40
                              41
                                   711
                                           5
 readr 40 41 318.8
                        50 50 1413
                                           5
    dt 40 80 9033.8 100 2605 42344
                                            5
rm(benchmark_results)
library(pryr)
size_base <- object_size(base)</pre>
size_readr <- object_size(readr)</pre>
size_fread <- object_size(dt)</pre>
```

```
print(data.frame(
    Method = c("Base R", "readr", "data.table"),
    Memory_MB = c(size_base, size_readr, size_fread)
))
```

```
Method Memory_MB
Base R 200.10 MB
readr 70.02 MB
data.table 63.47 MB
```

The fastest function of reading a compressed csv file is fread. The best memory efficiency function is fread().

read.csv() (Base R): Converts character columns to factors.

read_csv() (readr): Keeps character columns as character.

fread () (data.table): Automatically detects optimal types for speed & memory efficiency.

0.1.2 Q1.2 User-supplied data types

Re-ingest admissions.csv.gz by indicating appropriate column data types in read_csv. Does the run time change? How much memory does the result tibble use? (Hint: col_types argument in read_csv.)

```
file_path <- "~/mimic/hosp/admissions.csv.gz"</pre>
col_spec <- cols(</pre>
  subject_id = col_integer(),
 hadm_id = col_integer(),
 hospital_expire_flag = col_integer(),
  admission_type = col_character(),
  admission_location = col_character(),
 discharge_location = col_character(),
  insurance = col_character(),
  language = col_character(),
 marital_status = col_character(),
 race = col_character(),
  admittime = col_datetime(format = "%Y-%m-%d %H:%M:%S"),
  dischtime = col datetime(format = "%Y-%m-%d %H:%M:%S"),
 deathtime = col_datetime(format = "%Y-%m-%d %H:%M:%S"),
  edregtime = col datetime(format = "%Y-%m-%d %H:%M:%S"),
  edouttime = col_datetime(format = "%Y-%m-%d %H:%M:%S")
```

[1] "Optimized Tibble Memory Usage: 60.53 MB"

Yes, both the runtime and memory have changed. The running time has become shorter and the required memory for operation has also decreased.

0.2 Q2. Ingest big data files

Let us focus on a bigger file, labevents.csv.gz, which is about 130x bigger

than admissions.csv.gz.

```
ls -1 ~/mimic/hosp/labevents.csv.gz
```

-rwxrwxrwx 1 gewenqiang gewenqiang 2592909134 Jan 16 19:01 /home/gewenqiang/mimic/hosp/laber Display the first 10 lines of this file.

Solution:

```
zcat < ~/mimic/hosp/labevents.csv.gz | head -10</pre>
```

0.2.1 Q2.1 Ingest labevents.csv.gz by read_csv

Try to ingest labevents.csv.gz using read_csv. What happens? If it takes more than 3 minutes on your computer, then abort the program and report your findings.

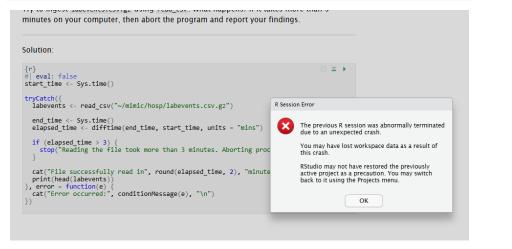

```
start_time <- Sys.time()</pre>
```

```
tryCatch({
    labevents <- read_csv("~/mimic/hosp/labevents.csv.gz")

end_time <- Sys.time()
    elapsed_time <- difftime(end_time, start_time, units = "mins")

if (elapsed_time > 3) {
    stop("Reading the file took more than 3 minutes. Aborting process.")
    }

cat("File successfully read in", round(elapsed_time, 2), "minutes.\n")
    print(head(labevents))
}, error = function(e) {
    cat("Error occurred:", conditionMessage(e), "\n")
})
```

Compressed CSV files (. gz) are read line by line, but will significantly expand in memory. Files like labevents. csv. gz (which may have compressed several GB) may expand to tens of GB during loading. My system doesn't have enough RAM, R will run out of memory and crash. The read_csv() function in the reader reads the entire dataset into memory before processing and ultimately attempts to load all its contents into memory. Unlike databases, it cannot efficiently stream data, resulting in high memory usage and ultimately causing computer memory crashes.

0.2.2 Q2.2 Ingest selected columns of labevents.csv.gz by read_csv

Try to ingest only columns subject_id, itemid, charttime, and valuenum in labevents.csv.gz using read_csv. Does this solve the ingestion issue? (Hint: col select argument in read csv.)

Solution:

```
start_time <- Sys.time()</pre>
tryCatch({
   labevents <- read_csv("~/mimic/hosp/labevents.csv.gz",</pre>
                                           col_select = c(subject_id, itemid,
                                                                       charttime, valuenum))
   end_time <- Sys.time()</pre>
   elapsed_time <- difftime(end_time, start_time, units = "mins")</pre>
   if (elapsed_time > 3) {
       stop("Reading the file took more than 3 minutes. Aborting process.")
   cat("File successfully read in", round(elapsed_time, 2), "minutes.\n")
   print(head(labevents))
}, error = function(e) {
   cat("Error occurred:", conditionMessage(e), "\n")
})
 cat("file successfully read in", round(elapsed_time, 2), "minutes.\n")
print(head(labevents))
, error = function(e) {
   cat("Error occurred:", conditionMessage(e), "\n")
                                                                                                             Q1.1 Speed,...

 Warning: One or more parsing issues, call `problems()` on your data frame for details,
                                                                                                             Q2.6 DuckDB
                                                          R Session Error
                                                                                                            Q3. Ingest a..
                                                                The previous R session was abnormally terminated due to an unexpected crash.
Q2.3 Ingest a subset of labevents.csv.gz
                                                                 You may have lost workspace data as a result of this crash.
                                                                 RStudio may not have restored the previously active project as a precaution. You may switch back to it using the Projects menu.
                                                                               ОК
```

NO, it is the same result with Q2.1.

Even if fewer columns are read_csv() will still load all content into RAM. If the dataset has billions of rows and the memory usage is still high, it can cause R to crash. Even if I only selected a few columns, I still have to decompress the entire file first. The labevents.csv.gz file has been compressed, and read_csv() must first decompress it into memory, resulting in high RAM usage. At the same time, unlike databases, read_csv() loads all data into memory at once. It does not support streaming, so even selecting fewer columns cannot fully alleviate

memory pressure.

0.2.3 Q2.3 Ingest a subset of labevents.csv.gz

Our first strategy to handle this big data file is to make a subset of the labevents data. Read the MIMIC documentation for the content in data file labevents.csv.

In later exercises, we will only be interested in the following lab items: creatinine (50912), potassium (50971), sodium (50983), chloride (50902), bicarbonate (50882), hematocrit (51221), white blood cell count (51301), and glucose (50931) and the following columns: subject_id, itemid, charttime, valuenum. Write a Bash command to extract these columns and rows from labevents.csv.gz and save the result to a new file labevents_filtered.csv.gz in the current working directory. (Hint: Use zcat < to pipe the output of labevents_filtered.csv.gz in Git! To save render time, you can put #| eval: false at the beginning of this code chunk. TA will change it to #| eval: true before rendering your qmd file.)

```
zcat < ~/mimic/hosp/labevents.csv.gz | awk -F',' '
BEGIN { OFS=","; print "subject_id,itemid,charttime,valuenum" }
NR == 1 {
    for (i=1; i<=NF; i++) { col[$i] = i }
    next
}
$col["itemid"] ~ /50912|50971|50983|50902|50882|51221|51301|50931/ {
    print $col["subject_id"],
    $col["itemid"], $col["charttime"], $col["valuenum"]
}</pre>
```

```
gzip > labevents_filtered.csv.gz
```

Display the first 10 lines of the new file labevents_filtered.csv.gz. How many lines are in this new file, excluding the header? How long does it take read_csv to ingest labevents_filtered.csv.gz?

Solution: # Display the first 10 rows of the file after skipping the header zcat labevents_filtered.csv.gz | tail -n +2 | head -10 # Count the total number of rows in the file (excluding the header) expr \$(zcat labevents_filtered.csv.gz | wc -1) - 1 10000032,50931,2180-03-23 11:51:00,95 10000032,50882,2180-03-23 11:51:00,27 10000032,50902,2180-03-23 11:51:00,101 10000032,50912,2180-03-23 11:51:00,0.4 10000032,50971,2180-03-23 11:51:00,3.7 10000032,50983,2180-03-23 11:51:00,136 10000032,51221,2180-03-23 11:51:00,45.4 10000032,51301,2180-03-23 11:51:00,3 10000032,51221,2180-05-06 22:25:00,42.6 10000032,51301,2180-05-06 22:25:00,5 32679896 # Start measuring time to evaluate performance start_time <- Sys.time()</pre> # Read the compressed CSV file using readr's read_csv() # This loads the dataset into memory, expanding the compressed file labevents_filtered <- read_csv("labevents_filtered.csv.gz")</pre> Rows: 32679896 Columns: 4 -- Column specification --Delimiter: "," dbl (3): subject_id, itemid, valuenum dttm (1): charttime i Use `spec()` to retrieve the full column specification for this data. i Specify the column types or set `show_col_types = FALSE` to quiet this message. # Stop measuring time end_time <- Sys.time()</pre>

Calculate elapsed time (time taken to read the file)

Time taken to read labevents_filtered.csv.gz: 11.72 seconds

```
# Free up memory by removing the tibble
rm(labevents_filtered)
rm(start_time,end_time,elapsed_time)
```

0.2.4 Q2.4 Ingest labevents.csv by Apache Arrow

Our second strategy is to use Apache Arrow for larger-than-memory data analytics. Unfortunately Arrow does not work with gz files directly. First decompress labevents.csv.gz to labevents.csv and put it in the current working directory (do not add it in git!). To save render time, put #| eval: false at the beginning of this code chunk. TA will change it to #| eval: true when rendering your qmd file.

Solution:

Then use arrow::open_dataset to ingest labevents.csv, select columns, and filter itemid as in Q2.3. How long does the ingest+select+filter process take? Display the number of rows and the first 10 rows of the result tibble, and make sure they match those in Q2.3. (Hint: use dplyr verbs for selecting columns and filtering rows.)

Write a few sentences to explain what is Apache Arrow. Imagine you want to explain it to a layman in an elevator.

Solution:

. .

```
# 1. Open the CSV dataset efficiently using Apache Arrow
labevents_ds <- open_dataset("~/biostat-203b-2025-winter/hw2/labevents.csv",
                             format = "csv")
start_time <- Sys.time()</pre>
# 2. Perform selection and filtering using dplyr functions
labevents_filtered_arrow <- labevents_ds %>%
  # Select only necessary columns
  select(subject_id, itemid, charttime, valuenum) %>%
  # Filter specific item IDs
  filter(itemid %in% c(50912, 50971, 50983, 50902,
                       50882, 51221, 51301, 50931)) %>%
  collect()#Bring the filtered results into memory as a tibble
end_time <- Sys.time()</pre>
elapsed_time <- difftime(end_time, start_time, units = "secs")</pre>
cat("Time taken for ingestion, selection, and filtering:",
    round(elapsed_time, 2), "seconds\n")
Time taken for ingestion, selection, and filtering: 34.63 seconds
cat("Number of rows in filtered dataset:",
    nrow(labevents_filtered_arrow), "\n")
Number of rows in filtered dataset: 32679896
print(head(labevents_filtered_arrow, 10))
# A tibble: 10 x 4
   subject_id itemid charttime
                                         valuenum
        <int> <int> <dttm>
                                             <dbl>
    10000032 50931 2180-03-23 04:51:00
                                              95
 1
    10000032 50882 2180-03-23 04:51:00
                                              27
    10000032 50902 2180-03-23 04:51:00
 3
                                             101
     10000032 50912 2180-03-23 04:51:00
                                              0.4
 5
    10000032 50971 2180-03-23 04:51:00
                                              3.7
    10000032 50983 2180-03-23 04:51:00
                                             136
 7
    10000032 51221 2180-03-23 04:51:00
                                             45.4
 8
     10000032 51301 2180-03-23 04:51:00
 9
     10000032 51221 2180-05-06 15:25:00
                                              42.6
10
     10000032 51301 2180-05-06 15:25:00
                                               5
# Free up memory by removing the tibble
rm(labevents_ds,labevents_filtered_arrow)
rm(start_time,end_time,elapsed_time)
```

Apache Arrow is like a high-speed data train. The traditional way of processing large datasets is like moving boxes one after another, while Arrow loads the entire train carriage at once, making the processing speed very fast. It saves data in a format that can be efficiently read by multiple tools (R, Python, Spark) without the need for additional conversions. This means that you can quickly analyze large datasets without running out of memory. If you handle big data, Arrow is your secret weapon for improving speed and efficiency.

0.2.5 Q2.5 Compress labevents.csv to Parquet format and ingest/select/filter

Re-write the csv file labevents.csv in the binary Parquet format (Hint: arrow::write_dataset.) How large is the Parquet file(s)? How long does the ingest+select+filter process of the Parquet file(s) take? Display the number of rows and the first 10 rows of the result tibble and make sure they match those in Q2.3. (Hint: use dplyr verbs for selecting columns and filtering rows.)

Write a few sentences to explain what is the Parquet format. Imagine you want to explain it to a layman in an elevator.

Solution:

Size of Parquet dataset: 2.6G /home/gewenqiang/biostat-203b-2025-winter/hw2/labevents_pard

```
rm(parquet_size)
# 1. Open the Parquet dataset (created previously)
parquet_data <- open_dataset(</pre>
  "~/biostat-203b-2025-winter/hw2/labevents_parquet",
 format = "parquet"
start_time <- Sys.time()</pre>
# 2. Time the ingest+select+filter process
result <- parquet_data %>%
  # Select only necessary columns
  select(subject_id, itemid, charttime, valuenum) %>%
  # Filter specific item IDs
  filter(itemid %in% c(50912, 50971, 50983, 50902,
                       50882, 51221, 51301, 50931)) %>%
  collect() #Bring the filtered results into memory as a tibble
end_time <- Sys.time()</pre>
elapsed_time <- difftime(end_time, start_time, units = "secs")</pre>
cat("Time taken for ingestion, selection, and filtering:",
    round(elapsed_time, 2), "seconds\n")
Time taken for ingestion, selection, and filtering: 6.7 seconds
rm(start_time,end_time,elapsed_time)
# 3. Display the number of rows and the first 10 rows
cat("Number of rows in result:", nrow(result), "\n")
Number of rows in result: 32679896
head(result, 10)
# A tibble: 10 x 4
   subject_id itemid charttime
                                          valuenum
                                             <dbl>
        <int> <int> <dttm>
     10000032 50931 2180-03-23 04:51:00
                                              95
 1
     10000032 50882 2180-03-23 04:51:00
 2
                                              27
 3
     10000032 50902 2180-03-23 04:51:00
                                             101
     10000032 50912 2180-03-23 04:51:00
                                               0.4
 5
     10000032 50971 2180-03-23 04:51:00
                                               3.7
     10000032 50983 2180-03-23 04:51:00
 6
                                             136
 7
     10000032 51221 2180-03-23 04:51:00
                                              45.4
 8
     10000032 51301 2180-03-23 04:51:00
                                               3
     10000032 51221 2180-05-06 15:25:00
                                              42.6
```

```
# Free up memory by removing the tibble
rm(result)
```

Parquet makes storing data faster and more efficient, especially for large datasets. Imagine you have a huge spreadsheet, but you only need a few columns instead of the entire file. Parquet does not read data line by line like traditional files such as CSV, but organizes data by column. This means that if you only need one column, it can quickly grab that part without loading everything else - it's a bit like searching for a book in a well-organized library instead of searching through a pile of messy files. It saves storage space and makes data analysis faster! Arrow is primarily an efficient in memory data format designed to accelerate tasks such as data analysis, machine learning, and database queries. Arrow enables data to be stored in RAM in an efficient format, avoiding repeated format conversions and improving query speed. Different languages can directly share data without conversion, with zero copy, greatly improving computational efficiency. Support for vectorized computing: Arrow enables CPU to process data in parallel, faster than traditional methods.

0.2.6 Q2.6 DuckDB

Ingest the Parquet file, convert it to a DuckDB table by arrow::to_duckdb, select columns, and filter rows as in Q2.5. How long does the ingest+convert+select+filter process take? Display the number of rows and the first 10 rows of the result tibble and make sure they match those in Q2.3. (Hint: use dplyr verbs for selecting columns and filtering rows.)

Write a few sentences to explain what is DuckDB. Imagine you want to explain it to a layman in an elevator.

```
# Start timer
start_time <- Sys.time()</pre>
# Perform selection, filtering, and enforce sorting
result <- tbl(con, "labevents_duckdb") %>%
  select(subject_id, itemid, charttime, valuenum) %>%
  filter(itemid %in% c(50912, 50971, 50983, 50902,
                       50882, 51221, 51301, 50931)) %>%
  #Bring the filtered results into memory as a tibble
  collect()
# Stop timer
end_time <- Sys.time()</pre>
elapsed_time <- difftime(end_time, start_time, units = "secs")</pre>
# Display processing time
cat("Ingest+convert+select+filter process took:",
    round(elapsed time, 2), "seconds\n")
rm(start_time,end_time,elapsed_time)
# Display number of rows and the first 10 rows
cat("Number of rows in result:", nrow(result), "\n")
# Explicitly sort by subject_id & time
print(result %>%
  arrange(subject_id, charttime) %>%
    head(10))
# Disconnect from DuckDB
dbDisconnect(con, shutdown = TRUE)
# Free up memory by removing the tibble
rm(result)
```

Imagine you have a bunch of files, and every time you need to find something, you have to flip through them one by one - this is how traditional databases work. On the other hand** DuckDB * * is like having a super fast librarian who will immediately give you what you need. It is designed for lightning fast data analysis, especially for large datasets, without the hassle of setting up a large database server. You can run it directly on your laptop, just like opening a spreadsheet, but its working speed is comparable to modern data tools. It's like giving your data a * * turbocharger * *, making complex queries feel as simple as Google search!

0.3 Q3. Ingest and filter chartevents.csv.gz

chartevents.csv.gz contains all the charted data available for a patient. During their ICU stay, the primary repository of a patient's information is their electronic chart. The itemid variable indicates a single measurement type in the database. The value variable is the value measured for itemid. The first 10 lines of chartevents.csv.gz are

```
zcat < ~/mimic/icu/chartevents.csv.gz | head -10

How many rows? 433 millions.(432997491)

zcat < ~/mimic/icu/chartevents.csv.gz | tail -n +2 | wc -1

d_items.csv.gz is the dictionary for the itemid in chartevents.csv.gz.

zcat < ~/mimic/icu/d_items.csv.gz | head -10</pre>
```

In later exercises, we are interested in the vitals for ICU patients: heart rate (220045), mean non-invasive blood pressure (220181), systolic non-invasive blood pressure (220179), body temperature in Fahrenheit (223761), and respiratory rate (220210). Retrieve a subset of chartevents.csv.gz only containing these items, using the favorite method you learnt in Q2.

Document the steps and show code. Display the number of rows and the first 10 rows of the result tibble.

Solution: Using the Apache Arrow

```
# Define file paths
chartevents_path <- "~/mimic/icu/chartevents.csv.gz"
parquet_path <- "~/biostat-203b-2025-winter/hw2/chartevents_vitals.parquet"
# Start timing
start_time <- Sys.time()

# Load and filter using Apache Arrow
chartevents_vitals <- open_dataset(chartevents_path, format = "csv") %>%
    select(subject_id, itemid, charttime,valuenum) %>%
    filter(itemid %in% c(220045, 220181, 220179, 223761, 220210)) %>%
    collect() # Convert to in-memory tibble

# End timing
end_time <- Sys.time()
elapsed_time <- difftime(end_time, start_time, units = "secs")

# Display processing time
cat("Time taken for filtering and saving:",</pre>
```

```
round(elapsed_time, 2), "seconds\n")
Time taken for filtering and saving: 102.94 seconds
rm(start_time,end_time,elapsed_time)
# Display number of rows in the filtered dataset
cat("Number of rows in filtered dataset:",
    nrow(chartevents_vitals), "\n")
Number of rows in filtered dataset: 30195426
# Display first 10 rows
print(head(chartevents_vitals, 10))
# A tibble: 10 x 4
   subject_id itemid charttime
                                         valuenum
        <int> <int> <dttm>
                                            <dbl>
    10000032 223761 2180-07-23 07:00:00
